ABSTRACT

A time varying current sensor is constructed using surface coils uniformly spaced around a central cavity adapted to receive the conductor through which the current to be measured flows. Accurate and uniform coil geometry is achieved using printed circuit board technology, thereby eliminating the high cost of precision toroidal coil winding. An optional hinge in the housing can allow the sensor to be easily installed on existing conductors without the need to disconnect and reconnect.

CORELESS CURRENT SENSOR

FIELD OF THE INVENTION

This invention relates to the measurement of time-varying electric currents, and more particularly to a coreless current sensor constructed using surface coils.

5 BACKGROUND OF THE INVENTION

In the prior art toroidal current transformers are well established as a method of measuring alternating currents. Referring now to Figure 1, these devices typically consist of a toroidal ferromagnetic core and a coil. The coil, consisting of insulated copper wire, is wound around the core, usually in a way that conforms to the toroidal
10 shape of the core. Alternating current in a conductor which passes through the center of the core creates a changing magnetic field which in turn induces a voltage at the coil terminals. This voltage provides a measure of the current in the conductor. If high accuracy is required or if the frequency is not constant, this voltage can be integrated by an analog integrator to give a more accurate measure of the current.

15 In theory if the coil and the core are toroidal and perfectly uniform and if the coil has an infinite number of turns, then the output voltage is unaffected by the position of the conductor passing through the center of the core. In other words the conductor does not need to be accurately centered to provide an accurate current measurement. In addition, the output voltage is unaffected by external fields produced by nearby
20 currents which do not flow through the inside of the core. In practice, as long as the core is uniform and has a high magnetic permeability, the coil does not need to be uniform and does not need to have very many turns. Nevertheless, it may be advantageous to have a large number of turns in order to produce a large signal.

There are a number of drawbacks to this kind of current sensor. The presence of the
25 ferromagnetic core will change the impedance of the AC conductor. Also, ferromagnetic cores can saturate and in the process produce non-linear signals. To prevent this, an electrical load or burden is often connected to the output terminals.

While such a sensor may be suitable for permanent installations, the need to string the conductor through the core can cause difficulties when retrofitting is required. Some current transformers have a split core to allow for easy installation. The problem with this is that the overall magnetic permeability of the core, and therefore the output
5 signal, is affected by small variations in the gaps where the two halves of the split core meet. This variation can be greatly reduced by making the gaps large, but the consequences of this is that the overall magnetic permeability of the core is greatly reduced and many more turns are then required in the coil to produce the same signal output. Also, if the magnetic permeability of the core is lower, then the uniformity of
10 the coil windings becomes more important.

Coil winding adds significantly to the cost of such a sensor. This cost is higher if more turns are required, and can be especially high if uniform winding is necessary. The winding of toroidal coils is especially expensive, particularly if a high-level of uniformity is required.

15 U.S. Patent 4,709,205, issued November 24, 1987 to Baurand et al., which is incorporated herein by reference, shows an attempt to address some of these problems. To eliminate saturation, hysteresis, and other non-linear effects of ferromagnetic cores, they produced a coreless sensor. To eliminate the cost of a toroidally wound core, they arrange four linear coils in the shape of a square to
20 enclose the AC conductor. This arrangement is somewhat sensitive to the position of the AC conductor and to external fields, and this is partly addressed by having a small opening for the conductor which restricts it from moving too far off center. This limits the range of conductor sizes that are suitable for use with this sensor. Also, there is a problematic trade-off between signal strength and the cost of the coils. If
25 the coils have few turns, they can be made relatively inexpensively, however, the signal output is then very weak. The signal output can be greatly increased by increasing the number turns, but this greatly increases the cost because a greater number of turns makes it more difficult to maintain a uniform winding. If the winding is not uniform, then the sensor is more sensitive to the position of the AC
30 conductor, and to external fields and this can lead to increased signal error. Even if the coils are perfectly wound for this geometry, there will be some sensitivity to these sources of error, because four linear coils do not form a true toroid.

U.S. Patent 5,414,400, issued May 9, 1995 to Gris et al., which is incorporated herein by reference, proposes a toroidal coil produced as a printed circuit board. While this greatly reduces the cost, it does suffer from certain difficulties. For example, the resolution of the printed circuit board production process limits the number of turns
5 possible for a given size of sensor. Furthermore, the capture area of each coil is very small, being limited by the radial length of the coil and the thickness of the printed circuit board. As a result, the signal from the sensor is very weak. They have proposed to address this by stacking a number of these printed circuit boards together and combining their signals. However, if a large number of circuit boards are used,
10 this detracts from the cost savings, and still results in a signal that is quite weak. This is because the geometry that they have chosen is quite inefficient in terms of the coil capture area achieved for the amount of printed circuit board required by the coil.

Another problem is that the AC conductor must be strung through the center of the sensor. This means that an existing circuit would have to be disconnected in order to
15 install the sensor. It would of course be possible to modify their printed circuit board design such that the toroid is split in two halves. However, to prevent shorting, it would be necessary to have a gap in the conductor traces where the two halves meet. Such a gap would be a source of non-uniformity and make the sensor sensitive to the position of the AC conductor and to external fields. The effect of the non-uniformity
20 could be reduced by making equivalent gaps evenly spaced around the circumference, but the effect of this would be to further reduce the already low amount of coil capture area.

U.S. Patent 6,271,655, issued August 7, 2001 to Weber et al., which is incorporated herein by reference, presents a current transformer based on a planar coil etched onto
25 a printed circuit board. Said planar coil is in fact a surface coil wherein in this case the surface on which the coil is disposed is planar (or a plane). While they have clearly presented a much more efficient coil geometry, this non-toroidal sensor is particularly sensitive to the position of the AC conductor. This problem is addressed by making the AC conductor a pair of traces on the opposite side of the printed circuit
30 board. Thus, motion of the AC conductor is not possible relative to the sense coil, and it is therefore prevented from being a source of error. While this is not a problem for a device which is assembled into a new product being manufactured, it does make

it very inconvenient for use as a general-purpose instrument, or as a sensor which needs to be retrofitted onto an existing conductor. Also, since the AC current must pass through a trace on a printed circuit board, this device is limited to measuring relatively small current levels. Furthermore, because this geometry does not even
5 begin to approach that of a toroid, it can be expected to have a very high level of sensitivity to external fields which cause noise.

SUMMARY OF THE INVENTION

It is an object of the present invention to provide a current sensor which is easily installed around an existing conductor without disconnecting the conductor. It is a
10 further object of the present invention to provide a current sensor which can accommodate a range of different conductor sizes. It is a yet further object of the present invention to provide a current sensor which is accurate, provides a relatively large signal output, is inexpensive to manufacture, reduces or eliminates some or all of the disadvantages associated with ferromagnetic cores, and is not sensitive to
15 external fields.

According to a preferred embodiment of this invention, a plurality of radially oriented surface coils are interconnected and arranged preferably substantially equally spaced around a central cavity and mounted in a hinged housing.

The present invention thus provides a current sensor comprising a plurality of surface
20 coils substantially uniformly spaced around a central cavity and substantially equidistant from said cavity, said cavity having been designed to accept a conductor through which the current to be measured flows, said coils being oriented to have symmetry with respect to the central axis of said cavity, said coils being electrically interconnected such that the output voltages of said coils are combined and applied to
25 the terminals of said sensor.

The present invention further provides a current sensor for measuring a time varying current flowing through a conductor, comprising: a plurality of surface coils, at least some of said coils being substantially uniformly spaced around a central cavity for receiving the conductor, and substantially equidistant from said cavity, said

substantially uniformly spaced coils being oriented substantially axially and radially relative to an axis of said cavity, at least some of said substantially uniformly spaced coils being electrically interconnected such that output voltages of said coils are combined and applied to output terminals of said sensor.

- 5 The present invention further provides, for a current sensor for measuring a time varying current flowing through a conductor, a coil comprising a substrate having a first surface and a second surface, the first surface being opposite to the second surface, the first surface being provided with at least one surface coil and the second surface being provided with at least one surface coil, wherein said surface coils on
10 both said surfaces are interconnected.

BRIEF DESCRIPTION OF THE DRAWINGS

In drawings which illustrate preferred embodiments of the invention by way of example only,

- Figure 1 is a perspective view of the components of a typical current transformer in
15 accordance with the prior art.

Figure 2 is a perspective view of the components of a current sensor in accordance with the present invention.

Figure 3 is an end elevation showing the arrangement of surface coils around the AC conductor in the preferred embodiment of the invention.

- 20 Figure 4 is an end elevation showing the hinged housing in the closed condition.

Figure 5 is an end elevation showing the hinged housing in an open condition for installation onto or removal from an existing conductor.

Figure 6 is a plan view of one face of a surface coil printed on a circuit board.

Figure 7 is a plan view of the opposite face of the printed circuit board of Figure 6.

Figure 9 is a perspective view of the sensor of the invention in a closed condition, having been fully installed onto an existing conductor.

Figure 10 is a schematic diagram showing the interconnection of the coils in the embodiment of Figure 4.

- 5 Figure 11 is an end elevation of an alternative embodiment of the invention using a flexible printed circuit.

Figure 12 is a plan view of one face of the flexible printed circuit of Figure 11.

Figure 13 is a plan view of the opposite face of the flexible printed circuit of Figure 11.

10 DETAILED DESCRIPTION OF THE INVENTION

Referring now to Figure 2, a plurality of surface coils 2 is arranged around a central cavity for receiving an AC current carrying conductor 3. For simplicity of manufacture, each coil 2 may be printed onto a circuit board 8 or other suitable substrate. Preferably the coils 2 are substantially equally or at least uniformly spaced.

- 15 Although optimum results may be obtained with equal spacing, near optimum results can be achieved with unequal spacing as long as the spacing is uniform. For example, a sensor with 18 surface coils with a spacing of 20 degrees between adjacent coils would be equally and uniformly spaced, but if the spacing alternated between 10 degrees and 30 degrees, e.g. 10,30,10,30... the coils would not be equally spaced, but
20 would still be uniformly spaced. To better understand why, one could imagine two sets of equally spaced coils being interleaved. Each set would possess the benefits of a toroidal geometry, and therefore would possess the same in combination with each other regardless of their relative orientation to each other.

Interconnecting wires 4 connect the coils 2 to each other, and to output terminals 5.

- 25 In the simplest case, each coil can be interconnected to its adjacent coil around the entire circumference with the exception of the two adjacent boards at which the signal output is measured. It is, however, advantageous to interconnect the coils in the manner illustrated in Figure 10, as two separate banks of coils. This allows for easier

installation around an existing conductor, and also enables the cancellation of the orthogonal loop formed by the interconnecting wires 4. Such an orthogonal loop would make the sensor more susceptible to external magnetic fields causing noise or signal error.

- 5 Alternating current in conductor 3 generates a varying magnetic field, which induces a voltage in the surface coils 2. Output terminals 5 receive the sum of the signal voltages produced by the individual coils 2.

In the embodiment illustrated in Figure 2 the surfaces on which the coils 2 are disposed are substantially planar. However, it will be appreciated that the coils 2 can
10 be disposed on curvate surfaces; for example the coils 2 can be printed or otherwise mounted on a curved circuit board or other substrate surface. It will also be appreciated that although in the embodiment shown each coil 2 is mounted onto the exterior face of the circuit board 8, it is also possible for the surface coil 2 to be printed on an interior surface of a multi-layer circuit board, or cast or embedded
15 within a substrate board, without affecting the performance of the device of the invention.

Referring now to Figure 3, it can be seen that the surface coils 2 are arranged in a radial orientation, like the spokes of a wheel around the AC conductor 3. The surface coils 2 are also oriented axially relative to an axis of the conductor 3. A small number
20 of coils 2 is shown for the sake of clarity, however a larger number of coils is possible and may be advantageous.

Referring now to Figure 4, the current sensor 1 comprises surface coils 2 mounted on circuit boards 8 that are in turn mounted in a hinged housing 6 which surrounds AC current carrying conductor 3. Twisted pair interconnect wires 4 connect the surface
25 coils 2 to signal cables coupled to output terminals.

Referring now to Figure 5, the hinged housing 6 of the current sensor 1 is opened to allow installation onto an existing AC conductor 3. The coil geometry makes it possible to keep the conductors of the surface coils 2 away from the mating surfaces
10 without introducing any imbalance or asymmetry, which could adversely affect the sensor accuracy. This is advantageous because coil conductors close to the mating
30 surfaces 10 would make the sensor vulnerable to scratches on these surfaces. Small

changes in the gaps between these surfaces will have a small effect on the sensor accuracy, however, this effect will be orders of magnitude less than it would be if there were a ferromagnetic core.

The same coil geometry also allows for a break in the interconnecting wires 4
5 between the two coils 2 adjacent to the portion of the housing 6 that opens. Thus, the sensor 1 can be placed over the conductor 3 without the interference of the interconnecting wires 4 forming an obstruction.

Referring now to Figure 6, a surface coil 2 is shown as a pattern of traces on one side of a printed circuit board 8. Referring now to Figure 7, a surface coil 2 on the
10 opposite side of the board 8 is shown. In these illustrations only a few loops for the coil are shown for the sake of clarity, but in practice it is possible to have many more loops. The two coils 2 on this printed circuit board are preferably connected to each other through a via, or plated drilled hole, in such a way that the opposed coils 2 are connected in series so that the voltages induced in the two coils 2 will reinforce each
15 other rather than cancel each other out. It can be seen from these figures that the amount of printed circuit board area occupied by a single turn of the surface coil is very small compared to the area enclosed by the turn. This is in contrast to the prior art toroidal printed circuit coil described earlier, wherein this is not the case. The advantage conferred by this is that a far greater coil capture area can be achieved for
20 the same amount of printed circuit board, or for the same size of sensor. Indeed, it can be shown that the present invention can be designed to be at least one order of magnitude superior in this regard. This translates into a signal output at least one order of magnitude larger, all other things being equal, for the size of the sensor presented in the prior art as referred to earlier, assuming a printed circuit board
25 thickness of one sixteenth of an inch. If a smaller printed circuit board thickness is used, this advantage becomes even more pronounced, because the number of surface coils 2, and therefore the number of turns possible in a given sensor size with the present invention, is inversely proportional to the printed circuit board thickness. These advantages are not shared by the prior art.

30 Figure 8 shows the coreless current sensor 1 in the process of being installed on conductor 3. In the preferred embodiment this is facilitated by the hinge 7 which allows the two sensor halves to spread apart. As a result there is no need to disconnect

and then reconnect conductor 3. In Figure 9, the hinge is closed and accurate current measurements with the sensor 1 are now possible. It should be noted that the sensor 1 is capable of picking up current in a conductor 3 with the hinge open, but unless the hinge is closed the measurement will not be accurate. The hinge 7 can be held closed
5 by a torsion spring, or latch, or other means (not shown), which will be readily apparent to those skilled in the art.

Referring now to Figure 10, it is shown in this schematic diagram how the surface coils 2 are connected to each other by interconnecting wires 4 and to the output wires, which lead to the output terminals 5. The surface coils 2 are all preferably connected
10 in series in such a way that all of the induced voltages will add to the final result and none will subtract from it. Although it is not shown in the schematic diagram for the sake of clarity, it may be advantageous if the interconnecting wires 4 are implemented as twisted pairs, as shown in Figures 4 and 5, as this may reduce spurious or interfering signals.

15 Referring now to Figure 11, an alternative embodiment is shown wherein the surface coils 2 are disposed on a flexible substrate, for example a flexible printed circuit substrate 9. One advantage of this is that the interconnections 4 between the surface coils 2 are part of the printed circuit substrate 9, thereby reducing assembly costs. While the spacing of the coils is not equal, given that the amount of spacing alternates
20 between larger and smaller, it is uniform, and therefore as explained earlier, the benefits of a toroidal geometry are maintained.

Referring now to Figure 12, one side of the flexible printed circuit substrate 9 is shown with an example of how the surface coils 2 can be arranged. Spaces for interconnections 4 are left between the surface coils 2. Due to the geometry of the
25 sensor 1, the interconnections 4 are shorter when closer to the center, but longer when farther away. The reverse side of the flexible printed circuit substrate 9 is shown in Figure 13. For the sake of clarity, not all coils 2 are shown in Figures 12 and 13, however, it will be understood that the same pattern repeats itself.

Preferred embodiments of the invention having been thus described by way of
30 example only, it will be appreciated that various modifications and adaptations may

be made without departing from the scope of the invention as set out in the appended claims.

CLAIMS

I claim:

1. A current sensor for measuring a time varying current flowing through a conductor, comprising:

a plurality of surface coils, at least some of said coils being substantially uniformly spaced around a central cavity for receiving the conductor, and substantially equidistant from said cavity, said substantially uniformly spaced coils being oriented substantially axially and radially relative to an axis of said cavity, at least some of said substantially uniformly spaced coils being electrically interconnected such that output voltages of said coils are combined and applied to output terminals of said sensor.
2. A current sensor according to claim 1 wherein at least one of said electrically interconnected surface coils comprises a printed circuit.
3. A current sensor according to claim 2 wherein at least one printed circuit has a first surface and a second surface, the first surface being opposite to the second surface, the first surface being provided with at least one surface coil.
4. A current sensor according to claim 3 wherein the second surface is provided with at least one surface coil.
5. A current sensor according to claim 4 wherein said surface coils on both said surfaces are interconnected.
6. A current sensor according to claim 5 wherein said surface coils on both said surfaces are connected in series.
7. A current sensor according to claim 1 wherein at least one of said surface coils includes a plurality of conductive loops.
8. A current sensor according to claim 1 wherein said current sensor further comprises a housing in which said surface coils are disposed.

9. A current sensor according to claim 8 wherein said housing is divided into at least two sections, such that said sections may be spread apart, to allow entry of said conductor into said cavity.
10. A current sensor according to claim 9 wherein said housing further comprises at least one hinge for pivotally connecting said sections.
11. A current sensor according to claim 9 comprising means for holding said housing sections in a closed position.
12. A current sensor according to claim 1 wherein said surface coils are interconnected in series such that the voltages are all additive.
13. A current sensor according to claim 1 wherein said surface coils are disposed on at least one flexible substrate.
14. A current sensor according to claim 13 wherein at least two coils are disposed on a single flexible substrate, and wherein said coils are interconnected by at least one interconnection disposed on the same substrate.
15. For a current sensor for measuring a time varying current flowing through a conductor, a coil comprising a substrate having a first surface and a second surface, the first surface being opposite to the second surface, the first surface being provided with at least one surface coil and the second surface being provided with at least one surface coil, wherein said surface coils on both said surfaces are interconnected.
16. A coil according to claim 15 wherein the substrate is substantially planar.
17. A coil according to claim 16 wherein said surface coils on both said surfaces are connected in series.
18. A coil according to claim 16 wherein at least one of said surface coils includes a plurality of conductive loops.
19. A coil according to claim 16 wherein the substrate is substantially rigid.
20. A coil according to claim 15 wherein the substrate is flexible.
